(54) Apparatus and methods for user identification to deny access or service to unauthorized users

(57) Apparatus for preventing unauthorized use of a voice dialing system and, particularly, a call forwarding feature associated with the system whereby system users may forward a telephone number respectively associated therewith to a remote location in order to receive phone calls at the remote location, comprises: a database for pre-storing telephone numbers of system users and for pre-storing acoustic models respectively representative of speech associated with each system user, the acoustic models respectively corresponding to the

telephone numbers; and a speaker identification module operatively coupled to the database for obtaining and decoding a speech sample from a potential system user during the potential users' attempt to make a telephone call, the speaker identification module comparing the decoded speech sample obtained with the pre-stored acoustic model associated with the telephone number dialed by the potential user; whereby if the decoded speech sample substantially matches the pre-stored acoustic model, then the phone call attempted by the potential user is terminated.

FIG. 1

Description

[0001] The present invention relates to apparatus and methods for user identification to deny access or service to unauthorized users and, more particularly, to apparatus and methods for speaker identification to deny access of a user to a voice dialing system for unauthorized purposes such as abusing a call forwarding service.

[0002] It is known that some voice dialing systems have a call forwarding or "follow-me" feature. Such a feature permits a person (user) having a telephone number (extension) within the voice dialing system, e.g., an employee, to forward his telephone calls, made to that number by a caller, to a remote location where he is present. In this way, a caller may reach that person seamlessly whether that person is at the original location of the number or at the remote location to which the number has been forwarded.

[0003] However, it is also known that such a call forwarding feature may be abused by an unscrupulous system user. For instance, such a person may desire to talk with another party whose telephone is external to the voice dialing system, e.g., a phone connected to a public switching telephone network (PSTN). By the user forwarding his number to the desired party's phone using the follow-me feature of the voice dialing system, the user may then dial his own telephone number from any location which will result in his reaching the desired party at the phone where the user's number was forwarded. In this way, the user fraudulently causes the system to treat the call as if it were an system-internal call rather than an outside call to an outside party and thus cause the system to incur the total cost of the call. Also, the actual destination of the phone call (i.e., the remote location) may be masked from the system since the telephone number dialed to reach that destination is the internal number of the system user.

[0004] The present invention provides apparatus and methods for biometric identification and/or non-biometric identification in order to deny use of a plurality of services by service users, as recited in the independent claims 1 and 9. The present invention also provides an apparatus for performing biometric identification and/or non-biometric identification in order to prevent a person from fraudulently using a company voice dialing system to make personal calls at the company's expense, as recited in independent claim 7.

[0005] Advantageously, in this manner, the present invention provides for identifying a requester of the services as a user on a list of unauthorized users (i.e., a black list). Thus, the users on the black list are denied access to the service, or provided with a phone number to call instead of being connected, or transferred to an operator, while any other user, not on the list, is permitted access. Accordingly, instead of having to identify and/or verify the actual identity of the requester, the present invention uniquely need only provide for identifying the requester as a person on the unauthorized users list.

[0006] These and other features and advantages of the present invention will become apparent from the following detailed description of illustrative embodiments thereof, which is to be read in connection with the accompanying drawings.

Figure 1 is a block diagram of a voice dialing system according to the present invention; and

Figure 2 is a flow chart of the call flow interaction between the voice dialing system and a user according to the present invention.

[0007] Referring to Figure 1, a voice dialing system 10 according to the present invention is shown. In such a preferred architecture, a database 12 and a biometric identification module 14 are operatively coupled to a network 16. An intelligent peripheral 18 is operatively coupled to the network 16 and to a private branch exchange (PBX) 20 and to a centrex CO 22 of a telephone provider which, itself, is operatively coupled to a public switching telephone network (PSTN) 24. The PBX 20 is also operatively coupled to the centrex CO 22. It is to be appreciated that the voice dialing system 10 is preferably implemented in a corporate setting whereby the PBX 20 is a private telecommunications exchange on the corporation's premises which provides a switching facility for telephones on extension lines within the premises (internal phones) and access to the public telephone network (external or outside phones), i.e., PSTN 24. Thus, telephones 26 and 28 are internal corporate phones of, for instance, employees, which are operatively coupled to the PBX 20. Such phones are said to be "behind" the PBX 20. On the other hand, telephones 30 and 32 are telephones outside of the corporate premises, for instance, residences or other businesses. It is to be understood that only a few telephones (internal phones 26 and 28 and external phones 30 and 32) are shown in Figure 1 for the sake of simplicity; however, the system of the invention is not so limited. Also, telephone 34, operatively coupled to the intelligent peripheral 18, represents operator service in the voice dialing system, as will be explained.

[0008] Normal telephone operation flow through the system 10 will now be described. For incoming calls, for instance, from telephone 32 to telephone 28, a call is passed through PSTN 24, to the centrex CO 22, to the PBX 20, to telephone 28. For outgoing calls, for instance, from telephone 28 to telephone 32, a caller utilizes the voice dialing features of the system. For example, a caller will state a name and the system will dial the phone number of the person associated with that name. Specifically, the request goes through the PBX 20, to the intelligent peripheral 18, through the network 16, and in accordance with the identification module 14 and database 12 as will be explained, the decision to connect the call back through the network and intelligent peripheral to the centrex CO 22 and the PSTN 24 to the

outside telephone 32 is made. Internal (extension to extension calls) between telephones 26 and 28 are accomplished internally through the PBX 20.

[0009] However, it is to be appreciated that a voice dialing system may permit a user to access the system from external telephones 30 and 32, by stating the name of party to be reached, as explained above. When using an external phone, access may be facilitated by a toll-free service which further aggravates the problem of users abusing a call forwarding feature, as will be explained below.

[0010] The voice dialing system 10 of the invention provides a call forwarding service or follow-me feature which is extremely useful to employees who are constantly mobile, that is, who travel and work away from the corporate premises during the course of the day. With this feature, the employee may effectively transfer the telephone number associated with his internal corporate phone to an external phone at the location where he is working that day. Thus, when an outside caller or an internal caller attempts to reach the employee at his regular phone number, the call is forwarded to the telephone at the remote location where he is working. However, as previously mentioned, conventional voice dialing systems which provide a similar call forwarding feature as just described are susceptible to abuse. Such conventional systems permit a dishonest employee to forward his telephone number to an outside party with whom he desires to communicate. Once his phone number is transferred to the outside party's phone, the employee may dial his own number from another internal phone or an external phone and the call will be forwarded to the party he wishes to contact. In this way, the employee fraudulently causes the corporate voice dialing system to treat the call as if it were a system-internal call rather than an outside call to an outside party and thus cause the system to incur the total cost of his personal call. Also, the actual destination of the phone call (i.e., the remote location of the outside party) is masked from the system since the telephone number dialed to reach that destination is the internal number of the employee.

[0011] voice dialing systems may come in many forms. Traditional voice dialing includes enrollment of 10-50 (or any number) of names and phone numbers and then a user states one of the enrolled names and is connected to the phone number associated with the enrolled name. Here, the issue of abusing the system is not controllable since the employee may change the phone number of any enrolled name and then call that name. But, in general, since the list of enrolled names is only accessible to that user, the operator of the intelligent peripheral is keenly aware of the costs associated with such users. Biometric speaker identification may be used here in addition to standard PIN (personal identification number) codes, as will be explained, to guarantee that indeed it is the user that is making the call.

[0012] Corporate voice dialers which have a pre-en-

rolled list of all company contacts (employees, etc.), and internal and external users, use this service to transfer to a contact. This service is particularly susceptible to abuse since the callers of the system are, in general, not identified since the set of callers may be the entire population. The user is allowed to change only his own record, i.e., a follow-me number, to facilitate access for callers of the system.

[0013] The voice dialing system 10 of the present invention, as exemplified in Figure 1, prevents such abuse from occurring. The call forwarding abuse-prevention operation of the voice dialing system 10 will be explained in conjunction with the call flow diagram shown in Figure 2. It is to be assumed that for the sake of the following explanation of the preferred operation that internal phone 26 is the dishonest employees corporate phone and external phone 30 is the phone of the party the employee seeks to fraudulently reach at the remote location.

[0014] The database 12 contains all the telephone numbers of the corporate employees who have the ability to use the call forwarding service. Also pre-stored in the database 12 are acoustic models which are respectively representative of speech associated with each of the subject employees. Each telephone number is associated with an acoustic model of the individual having that phone number or to an acoustic model representing a class of individuals who share similar acoustic characteristics. It is to be understood that the biometric identification module 14 which is preferably a speech/speaker recognition system generates the acoustic speech models. The module 14 may employ text-dependent or speaker-dependent identification technology as disclosed in the text: Chin-Hui Lee et al., "Automatic Speech and Speaker Recognition", Kluwer Academic Publisher, 1996. In such a case, enrollment (e.g., training data) is obtained when the user is asked to enter his name, for instance, when the voice dialing system prompts him for his name when using a voice mail feature. On the other hand, the module 14 may employ text-independent or speaker-independent identification technology as disclosed in U.S. Serial No. 08/788,471 (docket no. YO996-188) filed on January 28, 1997, entitled: "Text-independent Speaker Recognition for Command Disambiguity and Continuous Access Control". In this case, enrollment data is derived from previous usage of the system by the user.

[0015] It is to be understood that the speaker identification module 14 and the database 12 may be implemented in hardware, software or a combination thereof. Preferably, the module 14 and database 12 are implemented in software executed on an appropriately programmed general purpose digital computer. It is to be further understood that the other functional features associated with the voice dialing system of the invention may be implemented by module 14 and database 12 or by separate modules and databases on the same appropriately programmed computer.

[0016] Accordingly, the system operates as follows. The dishonest employee forwards his telephone number, associated with his internal phone 26, to the outside party's external phone 30 in a manner that is known in standard voice dialing systems. Next, the employee dials his own phone number from, for instance, internal phone 28 (step 100 of Fig. 2). The employee states his name at the request of the system (step 102 of Fig. 2).

[0017] The speaker identification module 14 receives the speech sample, provided by the employee stating his name, via the PBX 20, the intelligent peripheral 18 and the network 16. The intelligent peripheral 18 is preferably a device identified as a DirectTalk 6000 manufactured by IBM Corp. Further, the network 16 is preferably a local area network (LAN) and, preferably, a token-ring LAN. The speaker identification module 14 decodes the speech sample, in a known manner, and then compares the decoded speech sample with the acoustic model pre-stored in database 12 which corresponds to the telephone number dialed in step 100 (step 104 of Fig. 2). If the decoded speech sample is substantially close to the acoustic model (using comparison methods known to one of ordinary skill in the art of speech/speaker recognition), then it is determined that the speaker is the employee who is associated with the number dialed (step 106 of Fig. 2). Since, the likely reason for the employee to be dialing his own number from another internal phone is to fraudulently reach the outside party at phone 30, the voice dialing system terminates the call (step 108 of Fig. 2) or provides the employee with a phone number to dial to receive a directory assistance function. Thus, the dishonest employee is prevented from attempting to defraud the company for the cost of his personal calls.

[0018] In the event that a legitimate reason may arise that would necessitate an employee dialing his own extension (e.g., checking his voice mail), the preferred system may include an operator 34 (Fig. 1) to whom the employee would be transferred to if a match occurred in step 104 or the system may provide the employee with a phone number to dial to receive a directory assistance function. The operator 34 would then permit or deny the employee to continue the call. Of course on the other hand, if there is no substantial match between the decoded speech sample and the acoustic model, then the call is put through to the outside party (step 110 of Fig. 2).

[0019] It is to be understood that the present invention is not limited to speaker identification technology. Any type of biometric measure may be used to perform the identification. For example, such biometric attributes as fingerprints (obtained with a flat bed scanner), face recognition, iris recognition, signature recognition, hand geometry, face temperature infrared pattern or any combination thereof may be used. It is to be appreciated that the above list is not intended to be exhaustive, rather, other types of biometric attributes may be employed. For that matter, it is to be understood that non-biometric at-

tributes may be employed in addition to or in place of biometric attributes. For instance, conventional non-biometric attributes such as passwords, PINs, smart-cards, digital signatures, etc., may be used. It is to be appreciated that when non-biometric attributes are used, the biometric identification module 14 is not used, in that, the comparison of the non-biometric attribute (e.g., PIN) to the associated telephone number may be done by the intelligent peripheral 18 in cooperation with the database 12.

[0020] In general, during enrollment, the necessary biometric measures are taken for all the members of a black list. In a corporate environment, this means that all employees are enrolled and different black lists are built for different services based on, for example, a predetermined service participation schedule. During use, the biometrics measured when the service is requested are compared one by one with the biometrics stored on the black list in the database. When there is no close enough match, the service is granted. When there is a close enough match, service is denied and/or the request is forwarded to the operator. Such embodiments differ slightly from the previously explained preferred embodiment with respect to the comparison step in that the former embodiment merely compares a decoded speech sample (or other biometric measure) with one acoustic (biometric) model, i.e., the model associated with the phone number dialed, while the latter embodiments use the obtained voice sample (or other biometric measure) and compare it with all models in the black list for the particular service requested.

[0021] Other applications of the present invention may, for example, include: control of jury access to outside resources, prisoner access, control of child access to TV channels or computer internet web sites. Given the teachings of the invention, one of ordinary skill in the art will appreciate various other applications not explicitly mentioned herein.

[0022] In summary, provided is an apparatus for preventing unauthorized use of a voice dialing system and, particularly, a call forwarding feature associated with the system whereby system users may forward a telephone number respectively associated therewith to a remote location in order to receive phone calls at the remote location, comprises: a database for pre-storing telephone numbers of system users and for pre-storing acoustic models respectively representative of speech associated with each system user, the acoustic models respectively corresponding to the telephone numbers; and a speaker identification module operatively coupled to the database for obtaining and decoding a speech sample from a potential system user during the potential users' attempt to make a telephone call, the speaker identification module comparing the decoded speech sample obtained with the pre-stored acoustic model associated with the telephone number dialed by the potential user; whereby if the decoded speech sample substantially matches the pre-stored acoustic model, then

the phone call attempted by the potential user is terminated.

Claims

1. Apparatus for identifying service users in order to prevent unauthorized use of a plurality of services by service users, the apparatus comprising:

means for pre-storing one of a biometric attribute and a non-biometric attribute of at least a representative portion of the service users, the pre-storing means partitioning the pre-stored attributes into groups according to a predetermined service participation schedule with respect to the plurality of services;

means for obtaining one of the biometric attribute and the non-biometric attribute from a potential user during the potential users' attempt to access the service; and

means for comparing one of the obtained biometric attribute and the obtained non-biometric attribute with one of the pre-stored biometric attributes and the pre-stored non-biometric attributes within the groups;

whereby if one of the obtained biometric attribute and the obtained non-biometric attribute substantially matches one of a pre-stored biometric attribute and a pre-stored non-biometric attribute within one of the groups, then the apparatus denies the potential user access to the Particular service associated with the group containing the match.

2. The apparatus of Claim 1, wherein the at least one biometric attribute is speech and the obtaining means and comparing means include portions of a speaker identification module.
3. The apparatus of Claim 2, wherein the speaker identification module is text-independent whereby the at least one biometric attribute is representative of a class of service users.
4. The apparatus of Claim 1, wherein the groups of attributes partitioned by the pre-storing means are groups of users not authorized to access the service associated with the group.
5. Apparatus for preventing unauthorized use of a voice dialing system and, particularly, a call forwarding feature associated with the system whereby system users may forward a telephone number respectively associated therewith to a remote loca-

tion in order to receive phone calls at the remote location, the apparatus comprising:

a database for pre-storing telephone numbers of system users and for pre-storing acoustic models respectively representative of speech associated with each system user, the acoustic models respectively corresponding to the telephone numbers; and

a speaker identification module operatively coupled to the database for obtaining and decoding a speech sample from a potential system user during the potential users' attempt to make a telephone call, the speaker identification module comparing the decoded speech sample obtained with the pre-stored acoustic model associated with the telephone number dialed by the potential user;

whereby if the decoded speech sample substantially matches the pre-stored acoustic model, then the phone call attempted by the potential user is terminated.

6. The apparatus of Claim 5, wherein the speaker identification module is text-independent.
7. A method of identifying service users in order to prevent unauthorized use of a plurality of services by service users, the apparatus comprising:

(a) pre-storing one of a biometric attribute and a non-biometric attribute of at least a representative portion of the service users;

(b) partitioning the pre-stored attributes into groups according to a predetermined service participation schedule with respect to the plurality of services;

(c) obtaining one of the biometric attribute and the non-biometric attribute from a potential user during the potential users' attempt to access the service; and

(d) comparing one of the obtained biometric attribute and the obtained non-biometric attribute with one of the pre-stored biometric attributes and the pre-stored non-biometric attributes within the groups;

whereby if one of the obtained biometric attribute and the obtained non-biometric attribute substantially matches one of a pre-stored biometric attribute and a pre-stored non-biometric attribute within one of the groups, then the apparatus denies the potential user access to the particular service

associated with the group containing the match.

8. The method of Claim 7, wherein the at least one biometric attribute is speech and the obtaining and comparing steps are performed by a speaker identification module. 5
9. The apparatus of Claim 7, wherein the speaker identification module is text-independent whereby the at least one biometric attribute is representative of a class of service users. 10
10. The method of Claim 7, wherein the groups of attributes partitioned in the partitioning step are groups of users not authorized to access the service associated with the group. 15
